【Title of the Invention】 A Fuel Cell system

【Claim 1】 A fuel cell system having a configuration of
warming-up the fuel cell by a heat generated during the
5 occlusion of hydrogen in a hydrogen-occlusion alloy.

【Claim 2】 The fuel cell system according to Claim 1,
wherein cooling water for cooling the fuel cell is heated
by said generated heat to warm-up the fuel cell.

【Claim 3】 The fuel cell system according to Claim 1 or 2,
10 which has a configuration that when the temperature of the
fuel cell is not higher than a prescribed temperature, said
heat is generated to warm-up the fuel cell.

【Claim 4】 The fuel cell system according to any one of
claim 1 to 3, which has a configuration that the hydrogen
15 having been occluded in the hydrogen-occlusion alloy is
supplied to the fuel cell as fuel.

【Claim 5】 The fuel cell system according to Claim 4,
wherein said hydrogen is supplied to the fuel cell
depending upon the anode pressure of the fuel cell.

20 【Claim 6】 The fuel cell system according to Claim 4,
wherein said hydrogen is supplied to the fuel cell
depending upon the amount of hydrogen consumed by the fuel
cell.

【Claim 7】 The fuel cell system according to any one of
25 Claim 1 to 3, wherein the fuel cell starts the power

generation after the warming-up.

【Claim 8】 The fuel cell system according to Claim 3,
wherein the fuel cell generates power while warming-up the
fuel cell when the temperature of the fuel cell is within a
5 given temperature range, whose upper limit is said
prescribed temperature, and the warming-up is performed
with no power generation when the temperature of the fuel
cell is under the lower limit of said given temperature
range.

10 【Claim 9】 A fuel cell system comprising;

a fuel cell generating power in such a manner that
fuel gas and an oxidant are supplied to the fuel cell,

a hydrogen occlusion alloy storage tank storing the
hydrogen occlusion alloy,

15 a hydrogen tank for storing at least the hydrogen
supplied to a hydrogen-occlusion alloy storage tank, and

a warming-up means which performs a warm-up of said
fuel cell by supplying the heat generated in the hydrogen-
occlusion alloy during the course of storing said hydrogen
20 from said hydrogen storage alloy storing tank to said fuel
cell.

【Detailed Description of the Invention】

【0001】

【Technical Field to which the Invention Pertains】

25 The present invention relates to a warming-up a fuel

cell for starting the fuel cell remaining cold. More particularly, the invention concerns a fuel cell system for warming-up a fuel cell utilizing a hydrogen-occlusion alloy to start the fuel cell under a condition of low temperature.

5 【0002】

 【Prior Art】

 In recent years, from an ecological viewpoints such that the amount of carbon dioxide exhausted, which will lead to global warming, should be suppressed, a fuel cell electric vehicle (hereinafter abbreviated as "FCEV") has drawn attracted. FCEV carries a fuel cell (hereinafter abbreviated as "FC"), which generates power due to electrochemical reaction between hydrogen (H₂) and oxygen (O₂) in air, and supplies the power generated from FC to a driving motor at which driving force is brought about.

 【0003】

 FC exhibits its performances at the fullest extent at a given temperature. For example, in the case of a proton exchange membrane (PEM) type FC, the temperature for which FC exhibits the best performances is approximately 80°C, and if the temperature is lower than this, the power generation performance (electromotive force) is decreased. For this reason, in order to start FC at a winter season or at a cold district, FC should be warmed-up (i.e., FC should be heated to a prescribed temperature).

【0004】

The conventional warming-up of FC is conducted as follows:

(1) Warming-up of FC through Heater:

5 An electric heater is heated by a battery possessed by FCEV or a commercial electric power source provided on a garage or such to warm-up FC through the heat thus generated.

(2) Warming-up of FC through Hydrogen Combustor etc.:

10 Hydrogen or methanol (or gasoline) possessed by FCEV as a fuel (raw fuel) is supplied to and combusted in a catalytic combustor etc., the combustion heat being utilized to warm-up FC.

(3) Warming-up of FC utilizing Heat generated by FC

15 Itself:

Heat generated due to the electrochemical reaction between hydrogen and oxygen (so-called self heating of FC) at starting the power generation of FC is used to warm-up FC.

20 (4) Other Processes for Warming-up FC:

A heat accumulating agent or a heating agent is utilized to warm-up FC.

【0005】

【Means to be solved】

25 However, the warming-up of FC through the electric

heater described under Item (1) suffers from the drawback in terms of consumption of the battery. Also, at a low temperature, sufficient power can be supplied from the battery in some cases. In the case of utilizing the commercial electric power source, FC cannot warm-up at a portion where no commercial electric power source is provided, such as on the road. In the case of warming-up of FC through the hydrogen combustor or such described under Item (2), the fuel (raw fuel), which should be used for the power generation of FC, is unduly consumed. In the case of the warming-up of FC utilizing the heat generated by FC itself described under Item (3), FC cannot be warmed-up under the situation where FC cannot generate power. Also, the consumption of the fuel (raw) for warming-up FC is not preferable. The use of the heat accumulating agent or the heating agent mentioned under Item (4) is of the drawbacks that it is difficult to take heat at a necessary time and to the heat accumulating agent or a heating agent can be repeatedly used only with difficulty. That is, in the prior art, energy exclusively used for warming-up FC is required or energy, which should be used in the power generation, is wasted. Also, the use of the heater or the hydrogen combustor, etc, which can only be used in the warming-up, and the use of specialized heat accumulating agent or heating agent are problematic in terms of

enlarging the fuel cell system. The warming-up of FC should be conducted rapidly, which requires a large quantity of energy or an enlarged warming-up apparatus. However, the warming-up of FC must be carried out in a simple configuration with ease. These problems are applicable to a hydrogen automobile, which carries an internal combustion engine (apparatuses consuming hydrogen) utilizing hydrogen as fuel.

【0006】

An object of the present invention is, therefore, to provide a fuel cell system and a process for warming-up a fuel cell.

【0007】

【Means for Solving the Problems】

In light of the above situation, we have made serious studies in researches. As a result, taking notice of the fact that a hydrogen-occlusion alloy is heated during the occlusion of hydrogen, and the fact that the heat generated can be used repeatedly, we have accomplished the present invention.

Specifically, the fuel cell system according to claim 1 relates to a fuel cell system having a configuration of warming-up the fuel cell by a heat generated during the occlusion of hydrogen in a hydrogen-occlusion alloy.

A hydrogen-occlusion alloy (a metallic alloys for

hydrogen storage) is the alloy capable of absorbing hydrogen (occlude hydrogen gas) and capable of discharging the hydrogen therefrom in accordance with required cases. The hydrogen-occlusion alloy generates a heat when occluding hydrogen, while the hydrogen-occlusion alloy absorbs the heat when discharging hydrogen.

A fuel cell system according to the present invention is to warm-up the fuel cell by a heat generated during the occlusion of hydrogen in a hydrogen-occlusion alloy. Herein, a warming-up is defined as the operation for warming-up the fuel cell (the fuel cell system) when starting the fuel cell (the fuel cell system). In the present invention, however, a warming-up is defined as the operation that a heat is supplied to the fuel cell (the fuel cell system) under the condition of driving (an electric power is generating) so as to heat the fuel cell.

【0008】

The fuel cell system according to claim 2 relates to the fuel cell system of Claim 1, wherein cooling water for cooling the fuel cell is heated by said generated heat to warm-up the fuel cell.

The fuel cell generates the heat when an electric power is generating). For this reason, the fuel cell system has a cooling system to remove the generated heat by means of cooling water (coolant). In this configuration, cooling

water (coolant) in the cooling system provided on the fuel cell system is heated by the generated heat to warm-up the fuel cell.

【0009】

5 The fuel cell system according to claim 3 relates to the fuel cell system of Claim 1 or 2, which has a configuration that when the temperature of the fuel cell is not higher than a prescribed temperature, said heat is generated to warm-up the fuel cell.

10 In this configuration, when a warming-up is required, hydrogen is supplied to the hydrogen-occlusion alloy so as to generate the heat for warming-up the fuel cell. From a viewpoint of surely starting the fuel cell, the prescribed temperature is defined as the temperature enough to warm-up
15 the fuel cell. Said temperature can be determined in accordance with an internal temperature of the fuel cell and a temperature of cooling water of the fuel cell. In the preferred embodiment as described latter, the prescribed temperature is defined as 30°C in accordance with a
20 temperature of cooling water in the first cooling system of PEM type fuel cell.

【0010】

 The fuel cell system according to claim 4 relates to the fuel cell system of any one of claim 1 to 3, which has
25 a configuration that the hydrogen having been occluded in

the hydrogen-occlusion alloy is supplied to the fuel cell as fuel.

5 The fuel cell generates power by utilizing hydrogen as a fuel gas. In this configuration, the hydrogen having been occluded in the hydrogen-occlusion alloy is utilized for a power generation. When the hydrogen having been occluded in the hydrogen-occlusion alloy is discharged, the hydrogen-occlusion alloy is in the condition capable of occluding hydrogen again. Furthermore, When the hydrogen
10 having been occluded in the hydrogen-occlusion alloy is discharged, the heat is absorbed into the hydrogen-occlusion alloy. At this time, the fuel cell under the condition of driving can also be cooled due to the process.

【0011】

15 The fuel cell system according to claim 5 relates to the fuel cell system of Claim 4, wherein said hydrogen is supplied to the fuel cell depending upon the anode pressure of the fuel cell.

20 According to the configuration, when the anode pressure (hydrogen pressure) of the fuel cell is higher than the cathode pressure thereof, the amount of hydrogen supplied from the hydrogen-occlusion alloy (or the amount of hydrogen discharged from the hydrogen-occlusion alloy) is increased.

25 When the above configuration is applied to the

configuration of the embodiment as described later, the anode pressure (total amount of pressure): 1 is divided into 0.8 of the pressure supplied from the high pressure tank and 0.2 of the pressure supplied from MH tank.

5 In the fuel cell, the anode pressure is regulated to the prescribed value (the target value) in order to improve the ability of the power generation. For example, in the fuel cell disclosed in the embodiment of the present invention, when a load is high (the power generation is
10 high), the ability of the power generation can be improved by increasing the anode pressure. In this case, the hydrogen having been occluded in the hydrogen-occlusion alloy can be utilized in order to improve the anode pressure. Furthermore, when the anode pressure is varied,
15 the hydrogen having been occluded in the hydrogen-occlusion alloy can be utilized so as to prevent the anode pressure from varying. Specifically, the description of claim 5 "said hydrogen is supplied to the fuel cell depending upon the anode pressure of the fuel cell." has the meaning that
20 the hydrogen having been occluded in the hydrogen-occlusion alloy is supplied to the fuel cell (or is discharged from the fuel cell) and is not supplied to the fuel cell.

【0012】

25 The fuel cell system according to claim 6 relates to the fuel cell system of Claim 4, wherein said hydrogen is

supplied to the fuel cell depending upon the amount of hydrogen consumed by the fuel cell.

The amount of hydrogen consumed by the fuel cell (the amount of hydrogen supplied to the fuel cell) is increased
5 in accordance with the increase of the amount of the power generation.

According to the configuration, when the amount of hydrogen consumed by the fuel cell is increased, the amount of hydrogen supplied from the hydrogen occlusion alloy (the
10 amount of hydrogen discharged from the hydrogen occlusion alloy) is increased.

When the above configuration is applied to the configuration of the embodiment as described later, the amount of hydrogen consumed by the fuel cell (the amount of
15 hydrogen supplied to the fuel cell): 1 is divided into 0.8 of the pressure supplied from the high pressure tank and 0.2 of the pressure supplied from MH tank.

【0013】

The fuel cell system according to claim 7 relates to
20 the fuel cell system of any one of Claim 1 to 3, wherein the fuel cell starts the power generation after the warming-up.

For example, the fuel cell cannot generate power due to freeze-up and the like. In the above configuration, the
25 fuel cell starts the power generation after the warming-up.

【0014】

The fuel cell system according to claim 8 relates to the fuel cell system of claim 3, wherein the fuel cell generates power while warming-up the fuel cell when the
5 temperature of the fuel cell is within a given temperature range, whose upper limit is said prescribed temperature, and the warming-up is performed with no power generation when the temperature of the fuel cell is under the lower limit of said given temperature range.

10 According to the configuration, the fuel cell generates power while warming-up the fuel cell when the temperature of the fuel cell is within a given temperature range, and the warming-up is performed with no power generation due to a difficulty of the power generation when
15 the temperature of the fuel cell is under the lower limit of said given temperature range.

A given temperature of lower limit is defined as a low temperature (extremely low temperature) such that water generated in accordance with the power generation of the
20 fuel cell is frozen in the discharging passage.

Additionally, the given temperature is also defined as a low temperature (extremely low temperature) such that the electrolyte membrane of the fuel cell cannot be conducted to a proton (ion) due to the extremely low
25 temperature. In the embodiment of the present invention as

described later, the given temperature of lower limit is set to -20°C on the basis of the temperature of the first cooling water in PEM type fuel cell.

【0015】

5 A fuel cell system according to claim 9 comprises a fuel cell generating power in such a manner that fuel gas and an oxidant are supplied to the fuel cell, a hydrogen occlusion alloy storage tank for storing the hydrogen occlusion alloy, a hydrogen tank for storing at least
10 hydrogen supplied to a hydrogen-occlusion alloy storage tank, and a warming-up means which performs a warm-up of said fuel cell by supplying the heat generated in the hydrogen-occlusion alloy during the course of storing the hydrogen from said hydrogen storage alloy storing tank to
15 said fuel cell.

 According to the configuration, the fuel cell is warmed-up by utilizing the heat generated in the hydrogen occlusion alloy during the course of storing the hydrogen. Furthermore, in the embodiment as described later, the
20 hydrogen occlusion alloy storage tank corresponds to MH tank, the hydrogen tank corresponds to the high pressure tank, and the warm-up means corresponds to the warm-up system (the first cooling system), respectively.
 Additionally, the fuel gas corresponds to the hydrogen
25 supplied from the high pressure hydrogen tank, and the

oxidant corresponds to air supplied from an air compressor.

【0016】

【Embodiment of the present invention】

Embodiments of the present invention will now be
5 described by referring to the drawings.

<<Principal>>

First, the principal of warning-up FC according to
the present invention will be described.

FIG. 1 is a schematic view explaining a principal of
10 the warming-up of FC. FIG. 2 is a drawing showing one
example of the relation between an inner temperature of MH
tank and pressure characteristic. FIG. 3 is a time chart
on which the changes in the inner temperature of MH tank
are plotted by varying hydrogen pressure applied to MH tank.
15 The expression of the temperature in Celsius in FIG. 2 is
an indication for better understanding the temperature
indication by $1000/T$ (K) (the temperature indication by
Arrhenius plotting).

【0017】

20 Symbol 1 in FIG. 1 is a fuel cell (FC: hydrogen
consuming apparatus), which is subject of warming-up.
Symbol 2 is a high-pressure hydrogen tank which stores
hydrogen at a high pressure (for example approximately 25
MPa). Symbol 3 is an MH tank having a hydrogen-occlusion
25 metal accommodated therein, and possesses a high pressure,

gas-tight mechanism. Hydrogen is supplied to this MH tank 3 from the high-pressure hydrogen tank 2. MH tank 3 has an inner pressure of approximately 0.1 MPa (normal pressure) before warming-up, which is ready for occluding hydrogen.

5 【0018】

At the time of starting FC 1, hydrogen is supplied from the high-pressure tank 2 to the MH tank 3. At this time, the inner pressure of the MH tank 3 is increased and, simultaneously, the hydrogen-occlusion metal accommodated within the MH tank 3 occludes hydrogen to thereby generate heat, which increases the inner temperature of the MH tank 3. The relation between the inner pressure of the MH tank and the inner temperature of the MH tank is accorded with the inner temperature/pressure characteristics shown in Fig. 2. For instance, referring to Fig. 3, if the inner pressure of the MH tank 3 becomes 1 MPa, the inner temperature thereof becomes about 80°C. Also, if the inner pressure becomes 3 MPa, the inner temperature becomes about 105°C.

20 【0019】

The heat thus generated in the MH tank is transmitted to FC 1 via appropriate transmitting means, and warms-up FC 1. The transmission of the heat to FC 1 can be conducted in any manner of heat conduction, heat radiation and/or heat convection. The heat can also be transmitted either

in a direct heating manner or an indirect heating manner.

【0020】

As shown in FIG. 3, the inner temperature of the MH tank 3 is sharply increased to the maximum temperature when the pressure is applied, and subsequently, the temperature becomes constant without increasing the temperature (during the course of keeping the temperature at constant, hydrogen is continuously occluded). The hydrogen-occlusion alloy is heating as a whole volume (whole mass). From this fact, considering the MH tank 3 as what is called hydrogen-occlusion heater (MH heater), unlike the combusting heater or the electric heater, the MH heater occurs no overshooting during the course of the heating. What is more, this reaches the maximum temperature within a shortest period of time. Consequently, the MH heater, which can be handled in the easiest manner, can rapidly warm-up FC 1. As can be understood from FIG. 2 and Fig. 3, the temperature can be controlled by varying applied pressures. In this context, the MH heater can be assumed to be handled with very ease. The amount of calorie generated is varies depending upon type of the hydrogen-occlusion alloy accommodated within the MH tank 3 and is proportional to the amount of hydrogen occluded in a given hydrogen-occlusion alloy.

25 【0021】

FIG. 2 shows temperature-pressure characteristics of BBC (body centered cubic) type hydrogen-occlusion alloy. In the case where a typical BBC type hydrogen-occlusion alloy is accommodated within the MH tank, when the inner pressure of the MH tank becomes 3 MPa, the BBC type hydrogen-occlusion alloy occludes hydrogen in an amount of about 2.4 g (about 1.2 moles) per 100 g of alloy. In this case, the caloric value is approximately 15 kJ/g hydrogen, i.e., 15 kJ heat is generated when the BBC type hydrogen-occlusion alloy occlude 1 g of hydrogen. Examples of hydrogen-occlusion alloys which can be used in the present invention include, but are not restricted to:

AB₂ type alloys (Laves phase alloys), such as TiCr₂, (Zn, Ti) (Ni, Mn, V, Fe)₂ ...

AB₅ type alloys, such as LaNi₅, MmNi₅...

BCC type alloys, such as Ti-V-Cr, Ti-V-Mn ..., and other types such as Mg type alloys.

【0022】

The hydrogen-occlusion alloy can reversibly carry out occlusion and discharging of hydrogen. Accordingly, the hydrogen having been occluded in the hydrogen-occlusion alloy can be used as the fuel for FC 1 (hydrogen-consuming apparatus). Alternatively, the occluded hydrogen may also be returned to the high-pressure tank 2. Upon discharging the hydrogen, the hydrogen-occlusion alloy can occlude

hydrogen again, of course, with generating heat.

【0023】

Next, embodiments in which the FC system is applied to fuel cell electric vehicle (hereinafter abbreviated as
5 "FCEV").

【0024】

<<First Embodiment>>

In the first embodiment, while warming-up FC by the heat generated during occluding hydrogen into the hydrogen-
10 occlusion alloy, hydrogen is supplied to FC to generate power.

Fig. 4 is a partially perspective side view of FCEV on which FC system according to the first and second embodiments of the present invention. FIG. 5 is a block
15 diagram of FC system according to the first embodiment of the present invention.

【0025】

First, FCEV will be described.

FCEV shown in FIG. 4 has a configuration that an FC box is placed under the floor of the cabin. The FC box has
20 FC 10 (see FIG. 5) accommodated therein. A high-pressure tank 21 and an MH tank 31 are crosswise placed on the upper portions of the rear wheels. The heat generated in the MH tank 31 is made use of the warming-up of FC 10 via cooling
25 water passing through a piping making up a primary cooling

system (not shown).

【0026】

FC 10 is also connected to the high-pressure hydrogen tank 21 and the MH tank 31 via hydrogen supply pipes (not shown). FC 10 allows oxygen and hydrogen to be electrochemically reacted with each other to generate power. The electric power thus generated is supplied to a driving motor to run FCEV. FC used in the drawings is a proton exchange membrane (PEM) type FC, which is composed of appropriately 300 single cells comprising a membrane electrode assembly (MEA) comprising an electrode membrane sandwiched between an anode electrode and a cathode electrode, which is sandwiched between separators, all of which are not shown.

【0027】

Next, referring to FIG.5, a fuel cell system FC1 according to the present invention will now be described.

FC system F1 according to the first embodiment of the present invention comprises FC 10, a hydrogen supply system 20, a warming-up system 30, an air supply system 40, an electric-consumption system 50, and a control unit 60.

【0028】

As described previously, FC 10 is PEM type FC, into which hydrogen as the fuel and air as the oxidant gas are supplied to generate power. The electric power thus

generated in FC 10 is taken out via a voltage control unit (VCU) 51. VCU 51 is an electric power regulator having a limiter function, and regulates the electric current to be output from FC 10. The current outputted via VCU 51 is
5 supplied to load 52 such as a driving motor and accessories. The amount the output current is set depending upon amount of stepping a pedal (not shown), the current consumed by the accessories, and the like.

【0029】

10 The hydrogen-supplying system 20 serves as supplying of hydrogen as the fuel. For this reason, the hydrogen-supplying system 20 is comprises a high pressure hydrogen tank 21, a primary shut-off valve 22, a primary regulator 23, a secondary regulator 24, and an ejector 25 being
15 placed on the upstream of FC 10, as well as comprises a purge valve 26 placed on the downstream of FC 10. All of these devices are connected via pipes so that the hydrogen from the high-pressure tank 21, passing through the primary shut-off valve 22, the primary regulator 23, the secondary
20 regulator 24, and then the ejector 25, is supplied to FC 10 (anode pole). The unused hydrogen exhausted from FC 10 via the pipe is returned to the ejector 25 to be circulated for reuse. Alternatively, the unused hydrogen exhausted from FC 10 is discharged out of the hydrogen-supplying system 20
25 via the purge valve 26. The hydrogen-supplying system 20

also serves as supplying hydrogen to an MH tank 31 making up the warming-up system 30 which will be described later on. For this reason, the hydrogen-supplying system 20 possesses a branched pipe in order to supply hydrogen to the warming-up system 30, and store hydrogen in the high-pressure tank 21 at a pressure higher than the inner pressure of the MH tank 31.

【0030】

The high-pressure tank 21 is a lightweight tank made of a fiber-reinforced plastic (FRP), which secures pressure resistance and gas-sealing properties. The high-pressure tank 21, for example, has an inner volume of approximately 100 liters and is filled with hydrogen at the maximum pressure of 25 MPa.

In this embodiment, the high-pressure tank 21 also plays a role in what is called fuel tank.

【0031】

The first shut-off valve 22 is a dielectrically actuated ON-OFF valve. The first shut-off valve 22 is opened or closed based upon a signal from the control unit 60, and shuts off the hydrogen flowing from the high-pressure hydrogen tank 21 in its closed state. On the other hand, in the opened state, the shut-off valve 22 allows the hydrogen from the high-pressure hydrogen tank 21 for flowing toward the downstream side.

【0032】

The primary regulator 23 is a pressure-reducing valve, which reduces the pressure of the hydrogen supplied from the high-pressure tank 21, which is regulated to a prescribed pressure. The secondary regulator 24 is a pressure-reducing valve, which further reduces the pressure of the hydrogen having been reduced by the primary regulator 1, and which is regulated to a prescribed pressure. Into the secondary regulator 24 is inputted the pressure at the inlet of the cathode electrode as a pilot pressure (see FIG. 5). For this reason, the secondary regulator 24 is actuated so as to minimize the variation between differential pressures between the anode and the cathode. It is noted that due to the pressure at the inlet of the cathode inputted to the secondary regulator 24 as the pilot pressure, the supplying hydrogen to the anode of FC10 is performed after an air compressor 41, which will be described fully later on, is started, and then the pressure at the inlet of the cathode is increased. More specifically, after the primary regulator is in ON state and the air compressor 41 of the air-supplying system 40 is started, hydrogen is supplied from the hydrogen-supplying system to FC 10.

【0033】

The ejector 25 supplies the hydrogen having been

supplied from the secondary regulator 24 to the anode of FC 10. The ejector 25 is a circulating pump, which sucks the hydrogen having been used as the fuel gas, i.e., that exhausted from the anode of FC 10 to be circulated
5 utilizing the flowing of the hydrogen toward the anode. The use of the exhausted hydrogen by the circulation improves the fuel ratio.

【0034】

The purge valve 26 is a dielectrically actuated ON-OFF valve. The purge valve 26 is opened or closed based on
10 a signal from the control unit 60, and its closed state, it makes the exhausted hydrogen from FC 10 to flow towards the ejector 25. On the other hand, in the opened state, the purge valve 26 discharges the exhausted hydrogen from FC 10
15 out of the system.

【0035】

The pressure of the anode of FC 10 in the hydrogen-supplying system (the pressure at the inlet of the anode) is detected by a pressure sensor PA, and the detected
20 signal is configured to be sent to the control unit 60.

【0036】

The warming-up system 30 serves as supplying the heat generated in the MH tank 31 to FC 10 to warm-up FC 10. For this reason, the warming-up system 30 comprises the MH tank
25 31, a secondary shut-off valve 32, a tertiary shut-off

valve 33, an aperture 34, and a circulating pump 35. In this embodiment, the warming-up system 30 utilizes the primary cooling system C1 of FC 10.

【0037】

5 The portion passing through hydrogen of the warming-up system 30 is composed of the MH tank 31, the secondary shut-off valve 31, the aperture 34, and pipes for connecting them. On the other hand, the portion passing through the cooling water is composed of the MH tank 31
10 (the portion of jacket which will be described below), the circulating pump 35, FC 10, a heat exchanger HE making up the primary cooling stem C1 of FC 10, a thermostat valve TV, and the like, as well as the pipes connected to them (pipes of the primary cooling stem C1). The symbol C2 is the
15 secondary cooling system.

 Main devices making up the warming-up system 30 will now be described.

【0038】

 The MH tank 31 is a high-pressure gas-tight tank made
20 of an aluminum alloy having higher heat resistance and higher heat conductivity than those of FRP-made tank, and a hydrogen-occlusion alloy is accommodated within the MH tank 31. The MH tank 31 can occlude hydrogen at the maximum pressure for example from 3 to 5 MPa. The outside of the
25 MH tank 31 is covered with a water-cooling jacket, within

which the cooling water for FC 10 flows. Consequently, the heat generated during the course of occluding hydrogen in the hydrogen-occlusion alloy is transmitted to the cooling-water of FC 10. By circulating the cooling-water into FC 10, FC10 can be warmed-up. The amount of hydrogen charged within the MH tank 31 (which is in proportional to the inner volume of the MH tank 31) is set based upon the calorie required for warming-up of FC 10.

【0039】

10 The secondary shut-off valve 32 is a dielectrically actuated ON-OFF valve. The secondary shut-off valve 32 is opened or closed based on a signal from the control unit 60. In the closed state, the secondary shut-off valve 32 shuts off the current of the hydrogen flowing from the primary
15 regulator 23 towards the MH tank 31. On the other hand, in the opened state, the secondary shut-off valve 32 allows the hydrogen for flowing from the primary regulator 23 towards the MH tank 31. In usual state, the secondary shut-off valve 32 is in the closed state, but it becomes in
20 the opened state at the time of supplying hydrogen to the MH tank 31 in order to generate heat.

【0040】

 The tertiary shut-off valve 33 is a dielectrically actuated ON-OFF valve. The tertiary shut-off valve 33 is
25 opened or closed based on a signal from the control unit 60.

In the closed state, the tertiary shut-off valve 33 shuts off the hydrogen flowing from the MH tank 31 towards FC 10 (anode thereof). On the other hand, in the opened state, the tertiary shut-off valve 33 allows the hydrogen for
5 flowing from the MH tank 31 towards FC 10. In the normal state, the tertiary shut-off valve 33 is in the closed state, but it becomes in the opened state at the time of discharging the hydrogen occluded in the MH tank 31 to perform the power generation.

10 【0041】

The aperture 34 serves as pressure-reducing means, which regulates the pressure and the flow amount of hydrogen to be supplied from the MH tank 13 to FC 10 so as to be a pressure suitable for the pressure of the anode of
15 FC 10 and/or to be a flow amount suitable for supplying the hydrogen to the anode. The hydrogen entering in the aperture 34 is supplied to a portion between the ejector 25, configuring the hydrogen-supplying system 20, and the anode of FC 10 (the hydrogen may also be supplied between the
20 secondary regulator 24 and the ejector 25).

 【0042】

The circulating pump 35 serves as a pump for circulating the cooling water of the primary cooling system C1 for FC10. By the virtue of the circulating pump 35, the
25 cooling water is circulated in the order of the MH tank 31

(jacket portion thereof), the circulating pump 35, the thermostat valve TV (heat exchanger HE), and FC 10. A substance for decreasing the freezing point of the cooling water such as ethylene glycol is added to the cooling water.

5 【0043】

The temperature of the cooling water and the pressure of the MH tank 31 in the warming-up system are respectively detected by a thermo-sensor T and a pressure sensor PM. The detected signals are transferred to the control unit 60.

10 【0044】

In addition to taking the heat generated from the MH tank 31 to warm-up FC 10, the warming-up system 30 also plays a role in imparting the heat discharged generated in FC tank to the MK tank 31 to thereby promote the

15 discharging of the hydrogen occluded in the hydrogen-occlusion alloy at the discharge mode, which will be described later on. Upon discharging the hydrogen, the temperature of the hydrogen-occlusion alloy is decreased endothermically, in which case, the hydrogen-occlusion

20 alloy cannot occlude hydrogen. At the discharge mode, since the cooling water is cooled by the MH tank 31, the loads of the cooling systems C1 and C2 for FC 10 can be decreased. Specifically, the performance for cooling FC 10 is increased at the hydrogen-discharge mode.

25 【0045】

The air-supplying system 40 serving as supplying air as the oxidant gas to FC 10 possesses an air compressor 41.

The air compressor 41 comprises a supercharger driven by a motor, etc., and the revolution number of the motor is
5 controlled by a signal from the control unit 60 or such. Higher the revolution number is larger the amount of the air supplied to the cathode of FC 10. The air to be supplied to the cathode of the FC 10 is humidified in a humidifier (not shown). Off gas, which has been exhausted
10 from FC, flows into the humidifier to humidify the air, which is to be supplied to FC, and then discharged out of the system.

【0046】

The power-consuming system 50 is composed of VCU 51,
15 the load 52, and the like, as described previously.

【0047】

The control unit 60 plays a role in setting a target power generation of FC 10 based on θ th of stepping a pedal (not shown), the current consumed by the accessories, and
20 the like. Also, it plays a role in setting an amount of air to be supplied to FC 10 based on the target power generation (the revolution number of the motor of the air compressor 41). Also, it plays a role in setting an amount of hydrogen to be supplied from the MH tank 31 to FC 10
25 based on the target power generation (in proportional to

the amount of the hydrogen consumed) and the inner pressure of the MH tank 31. The amount of the hydrogen having been occluded in the hydrogen-occlusion alloy to be discharged (the amount of the hydrogen to be supplied to FC 10) is
5 controlled by the control unit 60 in such a manner that it controls the tertiary shut-off valve 33. The control unit 60 plays a role in restricting the target power generation based on the amount of the power outputted by FC 10 to set the current outputted from FC 10. VCU 51 takes the current
10 from FC 10 based on the amount of the output current. The control unit 60 also serves as judging whether or not FC 10 should be warmed-up at the time of starting (control of shifting a mode to a warming-up mode), as controlling the warming-up (control of a warming-up mode), and as
15 controlling the discharging of the occluded hydrogen (controlling of a discharge mode).

【0048】

Next, the control of shifting a mode to a warming-up mode, control of a warming-up mode, and the control of a
20 discharge mode will be described together with the operation of the above-mentioned fuel cell system F1.

FIG. 6 is a flowchart which controls the shifting a mode to a warming-up mode, which executes the warming-up of FC according to the first embodiment. FIG. 7 is a
25 flowchart which controls the warming-up in the first

embodiment. FIG. 8 is a flowchart which controls a discharge mode which discharge occluded hydrogen in the first embodiment.

【0049】

5 The shift to the warming-up mode is controlled as follows (see FIG. 6).

 In Step S1, when an ignition switch of FCEV (see FIG. 4) is turned on (IG.ON), the control unit 60 performs system checking (S2). If the control unit 60 judges
10 abnormality (No) as a result of the system, the control unit 60 shift the mode to an abnormal processing mode (S3). If the control unit 60 judges to be no abnormality (Yes), it judges whether or not the temperature of the cooling water is 30°C or less, which is the temperature required
15 for starting the warming-up mode, i.e., judges whether or not the temperature of the cooling water $\leq 30^{\circ}\text{C}$ (S4). If the temperature is more than 30°C, i.e., if the cooling water has a temperature exceeding 30°C, the mode is shifted to a stationary power generation mode (S5). At the
20 stationary mode, a power is generated in a usual manner without being shifted to the warming-up mode, because FC 10 can be started with causing little or no trouble if the temperature exceeds 30°C in the case of PEM type FC. On the other hand, if the temperature of the cooling water is
25 not more than 30°C, FC 10 is shifted to the warming-up mode

(S6).

【0050】

The warming-up mode is controlled and executed as follows (see FIG. 5 and FIG. 7).

5 It is noted that in the fuel cell system F1 according to the first embodiment of the present invention, the supplying of hydrogen to the MH tank 31 and the supplying of hydrogen to FC 10 can be carried out simultaneously. Consequently, at the warming-up in the first embodiment,
10 while supplying hydrogen to the MH tank 31, hydrogen is also supplied to FC 10 to generate power (power generation with warming-up).

【0051】

At the warming-up mode in the first embodiment, the
15 control unit 60 opens the primary and secondary shut-off valves 22 and 32 to be in their opened states, and closes the tertiary shut-off valve 33 to be in its closed state (S11). This supplies hydrogen (for warming-up FC 10) from the high-pressure tank 21 to the MH tank 31 via the primary
20 shut-off valve 22, the primary regulator 23, and the secondary shut-off valve 32. For a while, the inner pressure of the MH tank 31 is increased and the hydrogen-occlusion alloy occludes the hydrogen to generate heat. The heat is sharply generated and the inner temperature of
25 the MH tank 31, but the MH tank 31 is not overshoot as

described above (see FIG. 3). At this stage, since the air compressor 41 has not yet been started, the hydrogen is shut-off at the secondary regulator 24 and is never supplied to FC 10.

5 【0052】

Subsequently, the control unit 60 allows the circulating pump 35 making up the warming-up system 30, which also serves as a pump for circulating the cooling water of the primary cooling system C1 of FC 10, for
10 starting and, at the same time, allows the air compressor 41 for starting (S12), whereby the heat generated in the MH tank 31 is supplied to FC 10 via the cooling water. At this time, the air is also supplied to the cathode of FC 10. Upon supplying the air to the cathode, the pressure of the
15 cathode is increased. At this time from the secondary regulator 24 utilizing the pressure of the cathode as the pilot pressure as described above, the hydrogen is supplied to the anode of FC 10 (starting the power generation). The target power generation in FC 10 at this time, for example,
20 corresponds to the amount of electric power required for actuating the accessories such as the motor of the air compressor 41 and the circulating pump 35. Since no electric heater is used in this embodiment, it is not necessary to consider the addition of the consumption
25 electric power for the electric heater to the target power

generation. For this reason, the fuel ratio can be increased without expensing the valuable hydrogen for the additional device.

【0053】

5 Subsequently, the control unit 60 judges whether or not the temperature of the cooling water is lower than the temperature after the completion of the MH-heating. The temperature after MH heating, which has the meaning of the temperature for completing the supplying of the hydrogen
10 for warming-up FC 10 to the MH tank, is 32°C, which is set 2°C higher than the prescribed temperature for starting the warming-up. The reason why there is hysteresis between the prescribed temperature for supplying the hydrogen to the MH tank 31 to start the warming-up and the temperature after
15 the MH heating which completes the supplying of the hydrogen to the MH tank 31 is for carrying out the control in a stable manner.

【0054】

20 In Step 13, if the temperature of the cooling water is higher than the temperature after the MH heating (No), the secondary shut-off valve is closed to be in the closed state (S14), whereby the supplying of the hydrogen to the MH tank 31 from the high-pressure tank is stopped. This is due to the fact that the discharge mode will be smoothly
25 performed. Since FC 10 can be smoothly warmed-up through

the combination of the residual heat of the heat generated in the MH tank with the heat accompanying with the power generation of FC 10, no further heating is necessary.

【0055】

5 Then, the control unit 60 judges whether or not the temperature of the cooling water is higher than the temperature after the completion of warming-up (S15), and if the temperature of the cooling water exceeds the temperature after the completion of warming-up (Yes), the
10 mode is shifted to the discharge mode (S16). The temperature after the completion of the warming-up is here 70°C, which is the temperature capable of operating PEM type FC 10 in a usual manner. If the temperature of the cooling water is lower than the temperature after the
15 completion of warming-up (No), the judgment is continued until the temperature of the cooling water exceeds the temperature after the completion of warming-up, i.e., the warming-up mode is continued. The reason why the temperature after the MH heating and the temperature after
20 the completion of warming-up are individually set is that there is a possibility to bring about the situation where the warming-up cannot be rapidly carried out due to the cooling of FC 10 through the endothermic action of the hydrogen-occlusion alloy at the discharge mode. For this
25 reason, in this embodiment, the temperature after the

completion of the warming-up, which is the standard temperature for shifting the mode to the discharge mode, is set apart from the temperature after the completion of the MH heating.

5 【0056】

Returning to the description of Step S13, if the temperature of the cooling water is lower than the temperature after the completion of the MH heating in Step S13 (Yes), the control unit 60 judges whether or not the
10 inner pressure of the MH tank 31 is lower than the regulating pressure at the primary regulator 23 (S17). If the inner pressure of the MH tank 31 is equal to or higher than the regulating pressure at the primary regulator 23 (No), the secondary shut-off valve 32 is closed to be in
15 the closed state (S18), because the occlusion of the hydrogen into the hydrogen-occlusion alloy may be judged to be saturated. In order to continue the warming-up even after the secondary shut-off valve 32 is in the closed state, the control unit 60 is shifted to Step 20.

20 【0057】

In Step S17, if the inner pressure of the MH tank 31 is lower than the regulating pressure at the primary regulator 23 (Yes), in which case the MH tank can still occlude the hydrogen, the secondary shut-off valve 32 is
25 opened (S19). After the secondary shut-off valve 32 is in

the closed state in Step S18, the inner pressure of the MH tank 32 will be sometimes decreased due to the progress of the hydrogen-occlusion through the hydrogen-occlusion alloy. Even in such a case, i.e., even if the secondary shut-off valve 32 is in the closed state under the condition that the inner pressure of the MH tank 31 does not satisfy the regulating pressure of the primary regulator 23, such a case is compensated in Step 19 and, thus, the warming-up mode is appropriately executed.

10 **【0058】**

In Step S20, the situation is left standing for a prescribed period of time (for example, several seconds). In this course, the cooling water is circulated to warm-up FC 10. The reason why the situation is left standing for a prescribed period of time is that the control is stabilized. After the situation is left standing for a prescribed period of time in Step S20, the control unit 60 is returned to Step S13, and judges whether or not the supplying of hydrogen to the MH tank 31 is completed based on the temperature of the cooling water, followed by continuing the subsequent treatments.

20 **【0059】**

The discharge mode is controlled and executed as follows (see FIG. 5 and FIG. 8).

25 In the discharge mode, the control unit 60 calculates

the amount of the hydrogen to be consumed based on the target power generation of FC, and calculates the amount of the hydrogen supplied from the MH tank to FC, i.e., the hydrogen-discharging amount based on the calculated amount of the hydrogen to be consumed (S21). For example, the hydrogen-discharging amount is calculated so as to be 20% of the amount of the hydrogen to be consumed.

Alternatively, the hydrogen-discharging amount is calculated so as to offset the pressure variance of the anode. Based on the calculated hydrogen-discharging amount, the control unit 60 produces a signal for PWM-driving the tertiary shut-off valve 33 to PIM-drive the tertiary shut-off valve 33 (S22). This supplies the hydrogen from the MH tank 31 to the anode of FC 10 via the tertiary shut-off valve 33 and the aperture 34. Larger the amount of the hydrogen consumed is wider the pulse width of the signal (larger the duty ratio), increasing the amount of the hydrogen supplied from the MH tank 31 (the hydrogen-discharging amount). In order to have a reduced influence upon the flow of the hydrogen circulating through the anode of FC 10, the tertiary shut-off valve 33 is PMW-driven. The aperture 34 is provided in the same viewpoint, and reduces influence upon the flow of the hydrogen circulating through the anode of FC 10.

【0060】

Next, the control unit 60 judges whether or not the inner pressure of the MH tank 31 is larger than the pressure of the anode (S23). If the MH tank 31 is not larger than the pressure of the anode (No), the control unit 60 closes the tertiary shut-off valve 33 to be in the closed state, and is shifted to Step S26. This is for the preventing the hydrogen from flowing backward. On the other hand, if the inner pressure of the MH tank 31 is larger than the pressure of the anode (Yes), the control unit 60 then judges whether or not the pressure of the anode is equal to or less than the target pressure of the anode plus 20 KPa (S25).

【0061】

If the pressure of the anode exceeds the target pressure of the anode plus 20 KPa (Yes) in Step 25, the control unit 60 closes the tertiary shut-off valve 33 to be in the closed state, and then is shifted to Step 26. This is because a pressure of the anode appropriate for the power generation cannot be maintained if the pressure of the anode becomes too high. On the other hand, if the pressure of the anode is less than the target pressure of the anode plus 20 Kpa, which has no problem, the control unit 60 is shifted to Step S26 without closing the tertiary shut-off valve 33.

25 【0062】

Next, the control unit 60 judges whether or not the inner pressure of the MH tank 31 is equal to or more than 100 kPa (gauge pressure) (S26). If the inner pressure of the MH tank 31 is less than 100 kPa (No), the control unit
5 60 closes the tertiary shut-off valve 33 to be in the closed state (S27), and completes the control of the discharge mode (END). This is because the discharging of the hydrogen occluded in the hydrogen-occlusion alloy can be judged to be substantially completed if the inner
10 pressure of the MH tank 31 is less than the gauge pressure of 100 kPa, and an amount of the calorie can be secured for executing the subsequent warming-up mode.

【0063】

If the inner pressure of the MH tank 31 exceeds 100
15 kPa (Yes) in Step 26, the control unit 60 is returned to Step 21 to continue the discharge mode, because the hydrogen to be discharged has still been occluded in the MH tank 31, and the discharging of the hydrogen is preferred for carrying out the next warming-up with a larger amount
20 of the calorie in a better manner.

【0064】

Since the reaction of discharging the hydrogen having been occluded in the hydrogen-occlusion alloy is an endothermic reaction, the temperature of the hydrogen-
25 occlusion alloy (the inner pressure of the MH tank 31) is

decreased. For a while, the hydrogen cannot be discharged from the hydrogen-occlusion alloy any more as a rule. However, as in the case of this embodiment, by allowing the cooling water of FC 10 for flowing into the MH tank 31 (jacket portion thereof), the heater generated accompanying with the power generation of FC 10 is supplied to the hydrogen-occlusion alloy. Consequently, the hydrogen can be stably and surely taken from the MH tank 31. By discharging the whole of hydrogen from the MH tank 31, the amount of the calorie for the next warming-up can be secured.

【0065】

Next, referring to the time chart shown in FIG. 9, the actuation of the fuel cell system F1 of the first embodiment of the present invention will now be described (also see sometimes FIG. 5).

FIG. 9 shows a control time chart at the starting of FC system in the first embodiment.

【0066】

First, the first shut-off valve 22, the second shut-off valve 32 and the third shut-off valve 33 are closed in their closed states. The circulating pump 35 is stopped (Off). The temperature of the cooling water of FC 10 is less than 30°C, which is the prescribed temperature for starting the warming-up mode. The inner pressure of the MH

tank 31 is about 0 kPa (gauge pressure). Of course, FC 10 has not generated power (Off). In the discharging of the hydrogen from the MH tank 31 at the discharge mode, the amount of the hydrogen to be discharged is restricted not so as to have any influence upon the warming-up of FC 10.

【0067】

Under these conditions, an ignition switch of FCEV (see FIG. 4) is turned on (IG.ON). This executes the control as shown in FIG. 6, and, if no abnormality is found in the system and if the temperature of the cooling water is not higher than 30°C, the mode is shifted to the warming-up mode (System Check Clear).

【0068】

For the while, the control of the warming-up mode shown in FIG. 7 is executed, whereupon the primary shut-off valve 22 and the secondary shut-off valve 32 are opened in their opened state. At the same time, the circulating pump 35 is started (On). This supplies the hydrogen to the MH tank 3, increasing the inner pressure of the MH tank 31. Also, the temperature of the cooling water is increased and the cooling water having an increased temperature is circulated within the warming-up system 30 (primary cooling system C1), whereby the heat generated in the MH tank 31 warms up FC 10. In the time chart shown in FIG. 9, no power generation is carried out at this time (System Check

Clear). Specifically, the air compressor 41 has not yet been started.

【0069】

Upon supplying the hydrogen to the MH tank 31, the
5 temperature of the MH tank 31 immediately reaches the
maximum temperature and, thereafter, is maintained at a
constant temperature. As for the inner pressure of the MH
tank 31, it becomes constant at a high level after a
several period of time. During this course, the warming-up
10 is continued.

【0070】

In the time chart shown in FIG. 9, before the
completion of heating the MH tank 31, the power generation
by FC 10 is started (Stack power generation is started).
15 For this reason, the battery or such is utilized to start
the air compressor 41 and any other necessary accessories.
This supplies the hydrogen and oxygen to FC 10. Then, at
the time of increasing the voltage of FC (releasing
voltage), the load current is taken to the air compressor
20 and the like via VCU 51.

【0071】

Then, when the temperature of the cooling water
reaches 32°C, which is the temperature of the completion of
the MH-heating, in order to complete the supplying of the
25 hydrogen to the MH tank 31, the secondary shut-off valve 32

is closed to be the closed state. In this time chart, as soon as the completion of the warming-up, the hydrogen having been occluded in the MH tank 31 is discharged until the inner pressure becomes 0 kPa (at the fullest extent)

5 (discharge mode). In order to do so, the tertiary shut-off valve 33 is opened to be the opened state. As described previously, if the discharge mode is executed before the temperature of FC 10 reaches that at the stationary mode (e.g., 70-80°C), there is a possibility that the situation

10 would occur where the warming-up of FC cannot be carried out smoothly. However, as described above, in the time chart shown in FIG. 9, the amount of the hydrogen to be discharged is restricted not so as to have any influence upon the warming-up. Consequently, at the time when the

15 temperature of the cooling water reaches the temperature of the completion of the MK-heating, i.e., before FC 10 is sufficiently warmed up, the discharge mode is executed.

Also, in the case where the endothermic heat in the discharge mode is not supplied (transmitted) to FC 10, the

20 discharge mode can be executed at the time when the temperature of the cooling water reaches the temperature of the completion of the MK-heating.

【0072】

As described above, according to the first embodiment
25 of the present invention, FC 10 can be surely warmed-up by

utilizing the heat generated during the course of occluding the hydrogen in the hydrogen-occlusion alloy. Also, it is possible to discharge the hydrogen having been occluded, which can be used in the power generation as the fuel gas.

5 By discharging the hydrogen, the warming-up can be repeatedly carried out. Since the power generation is carried out while warming up FC 10 in this embodiment, the warming-up can be carried out in a rapid manner together with the self-heating of FC 10. Also, since the hydrogen
10 is supplied from the high-pressure tank 21 to the MH tank 31, the hydrogen for use in the warming-up can be incorporated if the high-pressure tank 21 is filled with hydrogen. In this context, differing from the specially providing a hydrogen tank only for the warming-up, the
15 complication of the hydrogen filling can be reduced.

The temperature of the MH tank 31 is accorded with the temperature-pressure characters of the hydrogen-occlusion alloy (drawings showing the characteristics between the inner temperature of the MH tank 31 and the
20 pressure thereof; see FIG. 2). If the type of the hydrogen-occlusion alloy and the hydrogen pressure applied are the same, the amount of the heat generated is in proportional to the amount of the hydrogen-occlusion alloy. Consequently, taking the type of the hydrogen-occlusion
25 alloy, the hydrogen pressure to be applied to the MH tank

31, and the amount of the hydrogen-occlusion alloy as parameters, the characteristics of the MH tank 1 (what is called hydrogen-occlusion type heater or MH heater) can be freely designed. On the other hand, at the time of
5 discharging the hydrogen having been occluded, the discharging amount thereof and the endothermic amount can be freely controlled taking the type of the hydrogen-occlusion alloy, the pressure, and the temperature as parameters.

10 Even if the inner pressure of the MH tank 31 is increased excessively, the amount of the hydrogen to be occluded (stored) is not so increased. On the other hand, from the viewpoint of the pressure resistance, the thickness of the MH tank 31 should be increased, in which
15 case, the heat generated in the interior of the MH tank 31 can be taken only with difficulty. In addition, the weight of the MH tank is increased accordingly. Furthermore, with regard to the discharging of the hydrogen having been occluded, the heat is supplied to the interior of the MH
20 tank 31 having an increased thickness in a difficult manner. From these points, the inner pressure of from 1 to 5 Mpa (more preferably from 1 to 3 MPa), is preferable in terms of the facts that hydrogen can be effectively occluded, that the thickness of the MH tank 31 may not be excessively
25 thick, as well as in terms of the heat transmission and

weight.

【0073】

<Second Embodiment>

Next, the second embodiment will be described.

5 The second embodiment of the present invention is an embodiment where FC is warmed up, and then FC generates power. The second embodiment is an embodiment that under the condition that the cooling water has the lowest temperature, e.g., not more than -20°C, FC is warmed-up.

10 Symbols for the portions which are common to those of the first embodiment are referred to the same symbols as those of the first embodiment, and the description of such portions will be omitted.

【0074】

15 FIG. 10 is a block diagram of FC system according to the second embodiment of the present invention.

As shown in FIG. 10, the fuel cell system F2 according to the second embodiment has no shut-off valve corresponding to the secondary shut-off valve 32 shown in
20 FIG. 5. In stead, the fuel cell system F2 according to the second embodiment has a three-way valve 27. The three-way valve 27 is a dielectrically actuated valve for switching the passages, and is switched to a stationary position or a warming-up position based on a signal from the control unit
25 60. When the three-way valve 27 is in the stationary

position, the hydrogen from the high-pressure tank 21 is directed towards the secondary regulator 24. On the other hand, when the three-way valve 27 is in the warming-up position, the hydrogen from the high-pressure tank 21 is
5 directed towards the MH tank 31. For this reason, when the hydrogen is being supplied to the MH tank 31, i.e., when FC 10 is under the warming-up, the hydrogen is never supplied to the FC 10 via the secondary regulator 24. On the other hand, when the hydrogen is supplied to FC 10 via the
10 secondary regulator 24, the hydrogen is never supplied to the MH tank 31.

The control unit 60 serves as judging whether or not FC 10 should be warmed-up at the time of the starting (control of being sifted to the warming-up mode),
15 controlling the warming-up (control of the warming-up mode), controlling the discharge of the hydrogen having been occluded (control of the discharge mode), and the like. In this respect, the roles of the control unit 60 are the same as those of the first embodiment.

20 【0075】

The control of the warming-up mode will be described together with the operation of the fuel cell system F2. However, since the control of being sifted to the warming-up mode and the control of the discharge mode in this
25 embodiment are the same as those of the first embodiment,

these descriptions will be omitted.

FIG. 11 is a flowchart which controls the warming-up mode.

【0076】

5 In the second embodiment, the warming-up mode is controlled and executed as follows (see FIG. 10 and FIG. 11).

 Since the three-way valve 27 is used in the second embodiment to switch the passage of the hydrogen, the
10 supplying of the hydrogen to the MH tank 31 and the supplying of the hydrogen to FC 10 cannot be carried out at the same time. Consequently, in the warming-up mode in the second embodiment, after the hydrogen is supplied to the MH tank (after the temperature becomes not lower than the
15 temperature after the completion of the MH-heating), the position of the tree-way valve 27 is switched to generate power.

【0077】

 In the warming-up mode in the second embodiment, the
20 control unit 60 opens the primary shut-off valve 23 to be in the opened state, and closes the tertiary shut-off valve 32 to be in the closed state. Furthermore, the control unit 60 positions the three-way valve 27 into the warming-up position (S31). This supplies the hydrogen from the
25 high-pressure tank 21 to the MH tank 31 via the primary

shut-off valve 22, the primary regulator 23, and the three-way valve 27, whereupon the inner pressure of the MH tank is increased and the hydrogen-occlusion alloy occlude the hydrogen, generating heat. The heating will rapidly occur and the inner temperature of the MH tank 31 is immediately increased, but the temperature is never overshoot as described previously (see FIG. 3).

【0078】

The control unit 60 starts a circulating pump 35 for the warming-up system 30, which also serves as the circulating pump for the primary cooking system C1 of FC 10 (S32). This supplies the heat generated in the MH tank 31 to FC 10 via the cooling water.

【0079】

Subsequently, the control unit 60 judges whether or not the temperature of the cooling water is lower than the temperature after the completion of the MH-heating (S33). The temperature after the completion of MH heating is 32°C, which is set 2°C higher than the prescribed temperature for starting the warming-up for the purpose of the stabilization of the control as in the first embodiment.

【0080】

If the temperature of the cooling water is not lower than the temperature after the completion of the NH-heating in Step 33 (No), the three-way valve 27 is positioned to

the stationary position (S34). This switches the passage, stopping the supplying of the hydrogen from the high-pressure tank 21 to the MH tank 31, while making it possible to supply the hydrogen to FC 10. The supplying of the hydrogen to the MH tank 31 is stopped for the purpose of smoothly executing the discharge mode. Since FC 10 can be smoothly warmed-up through the combination of the residual heat of the heat generated in the MH tank with the heat accompanying with the power generation of FC 10, no further heating is necessary. In relation to Step S39, which will be described fully later on, since the primary shut-off valve 22 is sometimes in the closed state, the operation of opening the primary shut-off valve 22 is included in Step S34.

【0081】

In Step S35, the control unit 60 starts the air compressor 41. This supplies the air to the cathode of FC 10, while supplying the hydrogen to the anode of FC 10 (starting power generation). The target power generation at this time is the same as that of the first embodiment. This makes it possible to smoothly warm-up FC 10 by the residual heat of the heat generated in the MH tank together with the heat accompanying with the power generation of FC 10.

【0082】

In Step S36, the control unit 60 judges whether or not the temperature of the cooling water is higher than the temperature after the completion of the warming-up. If the temperature of the cooling water exceeds the temperature
5 after the completion of the warming-up (Yes), the control unit 60 is shifted to the discharge mode (S37). The temperature after the completion of the warming-up is set at 70°C, which is the same temperature as that of the first embodiment. If the temperature of the cooling water does
10 not exceed the temperature after the completion of the warming-up (No), the judgment is continued until the temperature of the cooling water exceeds the temperature after the completion of the warming-up. Specifically, the warming-up is continued. The description of these points,
15 which are the same as those of the first embodiment, will be omitted.

【0083】

Returning to the description of Step S33, if the temperature of the cooling water is lower than the
20 temperature after the completion of the MH heating in Step S33 (Yes), the control unit 60 judges whether or not the inner pressure of the MH tank 31 is lower than the regulating pressure at the primary regulator 23 (S38). If the inner pressure of the MH tank 31 is equal to or higher
25 than the regulating pressure at the primary regulator 23

(No), the primary shut-off valve 22 is closed to be in the closed state (S39), because the occlusion of the hydrogen into the hydrogen-occlusion alloy may be judged to be saturated. In order to continue the warming-up even after the primary shut-off valve 22 is in the closed state, the control unit 60 is shifted to Step 41. It is also possible to have a configuration that in Step S39, the primary shut-off valve 39 is kept opening and the three-way valve 27 is switched to the stationary state.

10 【0084】

In Step S38, if the inner pressure of the MH tank 31 is lower than the regulating pressure at the primary regulator 23 (Yes), in which case the MH tank can still occlude the hydrogen, the primary shut-off valve 22 is opened (S40). After the primary shut-off valve 22 is in the closed state in Step S39, the inner pressure of the MH tank 32 will be sometimes decreased due to the progress of the hydrogen-occlusion through the hydrogen-occlusion alloy. Even in such a case, i.e., even if the primary shut-off valve 22 is in the closed state under the condition that the inner pressure of the MH tank 31 does not satisfy the regulating pressure of the primary regulator 23, such a case is compensated in Step 40 and, thus, the warming-up mode is appropriately executed.

25 【0085】

In Step S41, the situation is left standing for a prescribed period of time (for example, several seconds). In this course, the cooling water is circulated to warm-up FC 10. The reason why the situation is left standing for a prescribed period of time is that the control is stabilized. After the situation is left standing for a prescribed period of time in Step S41, the control unit 60 is returned to Step S33, and judges whether or not the supplying of hydrogen to the MH tank 31 is completed based on the temperature of the cooling water.

【0086】

In the fuel cell system F1 according to the first embodiment described previously, while supplying the hydrogen to the MH tank 31 (heating the MH tank 31), the hydrogen is also supplied to FC 10 to generate power. However, in the fuel cell system F2 according to this embodiment, FC 10 never generates power during the course of supplying the hydrogen to the MH tank 31, because the hydrogen flow is switched by means of the three-way valve.

【0087】

Next, the operation of the fuel cell system of the second embodiment will be described by reference to the time chart of FIG. 12 (also see FIG. 10).

FIG. 12 shows a control time chart at the starting of

FC system in the second embodiment.

【0088】

First, the first shut-off valve 22, and the three-way valve 27 is in the stationary position. The circulating pump 35 is stopped (Off). The temperature of the cooling water of FC 10 is less than 30°C, which is the prescribed temperature for starting the warming-up mode. The inner pressure of the MH tank 31 is about 0 kPa (gauge pressure). Of course, FC 10 has not generated power (Off).

10 【0089】

Under theses conditions, an ignition switch of FCEV (see FIG. 4) is turned on (IG.ON). This executes the control as shown in FIG. 6, and, if no abnormality is found in the system and if the temperature of the cooling water is not higher than 30°C, the mode is shifted to the warming-up mode (System Check Clear).

【0090】

For the while, the control of the warming-up mode shown in FIG. 11 is executed, whereupon the primary shut-off valve 22 is opened in the opened state. At the same time, the circulating pump 35 is started (On). This supplies the hydrogen to the MH tank 3, increasing the inner pressure of the MH tank 31. Also, the temperature of the cooling water is increased and the cooling water having an increased temperature is circulated within the warming-

up system 30 (primary cooling system C1), whereby the heat generated in the MH tank 31 warms up FC 10.

【0091】

Upon supplying the hydrogen to the MH tank 31, the
5 temperature of the MH tank 31 immediately reaches the
maximum temperature and, thereafter, is maintained at a
constant temperature. As for the inner pressure of the MH
tank 31, it becomes constant at a high level after a
several period of time. During this course, the warming-up
10 is continued.

【0092】

Then, when the temperature of the cooling water
reaches 32°C, which is the temperature of the completion of
the MH-heating, in order to complete the supplying of the
15 hydrogen to the MH tank 31, the three-way valve 27 is
switched to the stationary position. In the second
embodiment, when the tree-way valve 27 is switched to the
stationary position, the air compressor 41 is started to
supply the air to FC 10. The pressure of the cathode is
20 increased when the air compressor 41 is started, and the
hydrogen is supplied to the anode as in the first
embodiment whereby FC 10 starts the power generation.

【0093】

In the time chart shown in FIG. 12, a several period
25 after the completion of the warming-up, the hydrogen having

been occluded in the MH tank 31 is discharged (discharge mode). In order to do so, the tertiary shut-off valve 33 is opened to be the opened state. At the discharge mode, the control similar to the control in the flowchart of FIG. 8 is executed. In the discharge mode as in this embodiment that the primary cooling system C1 for FC 10 also serves as the warming-up system 30, preference is given to restrict the discharge amount of hydrogen in the discharge mode or to carry out the discharge mode after the warming-up of FC 10 has been perfectly completed to be shifted to the stationary power generation mode, as described above.

【0094】

As described above, according to the second embodiment of the present invention, FC 10 can be surely warmed-up by utilizing the heat generated during the course of occluding the hydrogen in the hydrogen-occlusion alloy. Also, it is possible to discharge the hydrogen having been occluded, which can be used in the power generation as the fuel gas. By discharging the hydrogen, the warming-up can be repeatedly carried out. Since the power generation is carried out while warming up FC 10 in this embodiment, the warming-up can be carried out in a rapid manner together with the self-heating of FC 10. According to this embodiment, even from the lowest temperature at which FC 10 cannot generate power, FC 10 can be securely warmed-up.

The consumption power required in this case is for the control unit 60, valves (22, 27, and 33), and the circulating pump 35. Consequently, differing from the conventional warming-up utilizing a heater, FC 10 can be warmed-up without excess loading of the battery. In this context, this embodiment is suitable for warming-up FC 10 at the coldest place, where the electromotive force is lowered.

【0095】

10 <<Third Embodiment>>

Next, the third embodiment will be described (see FIG. 5 and the like).

The third embodiment of the present invention is an embodiment where FC 10 generates power while warming-up FC 10 (power generation with warming-up, and in the case of the lowest temperature (lower than the lower limit of a prescribed temperature), FC does not generate power, only the warming-up of FC 10 is carried out. For this reason, the control unit 60 of the fuel cell system F3 (see FIG. 5) according to the third embodiment supply the hydrogen both to the MH tank 31 and FC 10 to generate power with warming-up if the temperature of the cooling water is with the prescribed range of from -20°C to 30°C. On the other hand, if the temperature of the cooling water is less than -20°C (the lowest temperature), the control unit 60 supplies the

hydrogen only to the MH tank to warm-up FC.

【0096】

The configuration of the devices making up the system (warming-up apparatus) according to the third embodiment is
5 the same as that in the first embodiment and, thus, the description thereof will be omitted.

Referring to FIG. 13, the actuation of the fuel cell system F3 according to the third embodiment will be described.

10 FIG. 13 is a flowchart which controls the shifting a mode to a warming-up mode, which executes the warming-up of FC according to the third embodiment.

The description of Steps S1 to S5 in FIG. 13, which are the same as those in the flowchart for controlling the
15 mode being shifted to the warming-up mode for warming-up FC 10 in the first embodiment, are omitted.

【0097】

In Step S4, if the temperature of the cooling water is less than 30°C, the control unit 60 judges whether or
20 not the temperature of the cooling water is less than -20°C in Step S7. If the temperature of the cooling water is not less than -20°C (No), the warming-up mode while warming-up FC 10 (with warming-up) is executed (S8). Conversely, if the temperature of the cooling water is less than -20°C
25 (Yes), which is the lowest temperature, the warming-up mode

without warming-up FC 10 (without warming-up) is executed (S9). In the warming-up mode in Step S9, at the time of the temperature of the cooling water for FC 10 being not less than -20°C, the air compressor 41 is started. With
5 starting the air compressor 41, the air and hydrogen are supplied to FC to start FC 10 for generating power.

【0098】

According to the third embodiment just mentioned, even at the lowest temperature, which can never make a
10 power generation, FC 10 can be surely warmed-up.

【0099】

While the embodiments of the present invention have been described, it should be noted that the present invention is not restricted thereto, and various
15 modification can be made without departing from the scope and the sprits of the present invention.

For example, whereas FC 10 is warmed-up by the cooling water, the heat generated during the course of the occlusion of the hydrogen in the hydrogen-occlusion alloy
20 is directed to the FC box (see FIG. 4), and by the heating the FC box, FC 10 may be warmed-up. Also, whereas the MH tank 31 is configured to be disposed at the rear portion of FCEV, it may be configured to be accommodated within the FC box. Also, the fuel gas and/or air may be humidified for
25 use as the heating medium. Also, in the first and second

embodiment, the tertiary shut-off valve 33 is PWM driven and the aperture 34 is provided, but the aperture may be omitted. Alternatively, if the aperture is provided, the positions of the tertiary shut-off valve 33 and that of the aperture 34 may be replaced, and the tertiary valve 34 is made up by a usual ON-OFF valve. Also, the positions of the tertiary shut-off valve 33 and that of the aperture 34 may be replaced to dispose the aperture on the upstream side. Also, while the prescribed temperature range for the power generation with warming-up is within the temperature from -20°C to 30°C, the prescribed temperature may be freely set. For example, the lower limit may be set at -35°C, while the upper limit may be set at 20°C.

【0100】

While the hydrogen discharged from the MH tank 31 is supplied to the downstream side of the ejector 25, it may be supplied to the upstream side thereof. Also, the discharge of the hydrogen having been occluded may not be carried out at the same time of the completion of the warming-up mode, and may be carried out until FCEV is stopped. Also, in the second embodiment, the tree-way valve 27 has been utilized for the description, but the passage switching means is not restricted to the three-way valve. For example, the passage switching means may be composed of a combination of (1) a shut-off valve which

shuts off the hydrogen flow from the primary regulator 23 towards the secondary regulator 24, and a shut-off valve which shuts off the hydrogen flow from the primary regulator 23 to the MH tank (corresponding to the secondary shut-off valve in the first embodiment). While the power generation is started at the temperature exceeding 32°C in the second embodiment, it may be started at the time of exceeding -20°C. In this case, the passage switching valve described above is disposed in place of the three-way valve 27. Also, in the third embodiment, the power generation may be started at the time which the temperature of the cooling water reaches the temperature after the completion of the MH heating 32°C). Also, while these embodiments exemplify PEM type FC 10, the present invention is not restricted to PEM type FC 10. Also, the fuel cell carried electric vehicle (FCEV) has been described, a hydrogen vehicle which carries a hydrogen engine (hydrogen-consumption apparatus) utilizing hydrogen as fuel is applicable to the present invention.

【0101】

【Effects of the Invention】

The present invention has been described as aforementioned manner.

According to claim 1 of the present invention, the fuel cell is warmed-up by utilizing the heat generated in

the hydrogen occlusion alloy during the course of storing the hydrogen as the fuel of the fuel cell. Thus, it would not be necessary to prepare the extra energy enough to warm-up the fuel cell so that the mechanism of the fuel
5 cell system is not complicated. Additionally, the hydrogen occlusion alloy can reversibly repeat an occlusion of hydrogen / a discharging of hydrogen. Thus, whenever the fuel cell is warmed-up, the fuel cell can be started at a low temperature. Furthermore, the over shoot never occurs
10 in the fuel cell so as to easily perform a warm-up of the fuel cell and easily handle the fuel cell.

According to claim 2 of the present invention, a warming-up of the fuel cell is performed by utilizing cooling water as heating medium in the cooling system
15 provided on the fuel cell system. Thus, a mechanism of the warming-up system can be drastically simplified.

For example, a simple mechanism enables the fuel cell to be lightened so as to improve a mileage of vehicles

According to claim 3 of the present invention, the
20 warming-up of the fuel cell can be performed on the basis of the temperature of the fuel cell whenever the fuel cell needs to be warmed-up.

According to claim 4 of the present invention, the hydrogen having been occluded in the hydrogen-occlusion
25 alloy is supplied to the fuel cell. Thus, the hydrogen is

not wastefully used so as to improve the mileage of vehicles.

According to claim 5 of the present invention, the hydrogen having been occluded in the hydrogen-occlusion alloy is supplied to the fuel cell depending upon the anode pressure of the fuel cell. Thus, the hydrogen can be supplied to the fuel cell depending upon the driving condition of the fuel cell so that power can be generated in a stable manner.

10 According to claim 6 of the present invention, the hydrogen having been occluded in the hydrogen-occlusion alloy depending upon the hydrogen consumption amount consumed by the fuel cell is supplied to the fuel cell. Thus, the hydrogen can be supplied to the fuel cell
15 depending upon the driving condition of the fuel cell so that power can be generated in a stable manner.

According to claim 7 of the present invention, power is generated after the warming-up is performed. Thus, the fuel cell can be surely started.

20 According to claim 8 of the present invention, the fuel cell generates power while warming-up the fuel cell when the temperature of the fuel cell is within a given temperature range. Thus, warming-up of the fuel cell can be rapidly performed by the fuel cell itself.

25 According to claim 9 of the present invention, like

the invention described in claim 1, the fuel cell is warmed-up by utilizing the heat generated in the hydrogen occlusion alloy during the course of storing the hydrogen. Thus, it would not be necessary to prepare the extra energy
5 enough to warm-up the fuel cell so that the mechanism of the fuel cell system is not complicated. Additionally, the hydrogen occlusion alloy can reversibly repeat an occlusion of hydrogen / a discharging of hydrogen. Thus, the fuel cell is warmed-up whenever it is required.

5 **【Name of Document】** Abstract

【Abstract】

【Object】 Providing a fuel cell system for warming-up a
fuel cell utilizing a hydrogen-occlusion alloy to start the
5 fuel cell under a condition of low temperature.

【Means for Solution】

hydrogen stored in a high-pressure tank 21 is supplied to
an MH tank 31 to be occluded. Cooling water of a cooling
system C1 for a fuel cell 10 is heated through the heat
10 generated at this time to warm-up the fuel cell. by such a
configuration, the fuel cell can be warmed up without
consuming the valuable hydrogen.
